1 Calculating Probability Using R

As we gradually introduce more and more statistic concepts and tests, we will need to do quite a few complicated calculations. Some of them cannot be computed by hand or regular calculator; others can, but there are just too many steps and they are error-prone. Therefore, we introduce how to use the programming language \mathbf{R} for the calculation of probabilities and related stuff. You don't really need to know how to write scripts in \mathbf{R} . For now, you can just use it as a calculator.

Go to the SUSTech mirror of R: https://mirrors.sustech.edu.cn/CRAN. Download and install the program based on your operating system.

If you open the program, you will probably see a window like shown in the screenshot on the right-handside. The ">" mark that I highlighted at the bottom is your "prompt", where you can type commands. Like I said before, for now, you don't really need to know how to write scripts in **R**. You just use it as a probability calculator. Later on, we will see how to perform statistical tests.

Since we already introduced how

to calculate probability using **Excel**, we will use that as the comparison. Let's start with simple examples of three different distributions: B(6, 0.3), Pois(2) and $\mathcal{N}(1,4)$. In **R**, if you want the cumulative probability, the function always starts with "p"; if you want the probability mass/density, the function always starts with "d". For example, pbinom, ppois, and pnorm will give us the cumulative probability of the binomial, Poisson and normal distributions, respectively. They are like the *.DIST functions in **Excel** with the "cumulative" option set to "TRUE or 1".

Lecture 20

Similarly, the dbinom, dpois will give the exact probability of a binomial and Poisson distributions respectively, and dnorm will give you the probability density of a normal distribution. They are like the *.DIST functions in Excel with the "cumulative" option set to "FALSE or 0".

If you want to do the opposite, that is, provide the cumulative probability and return the value of the random variable, the function always starts with "q", like qbinom, qpois and qnorm. They are like the *.INV functions in Excel.

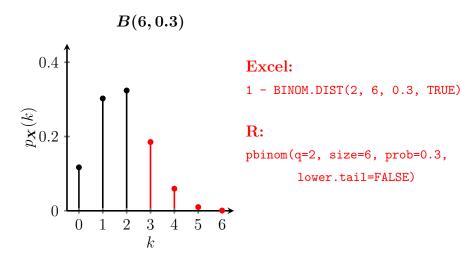

Just to give you some visual explanation of typical calculations:

3 More Complicated Distributions

For more complicated distributions that we will encounter later in the course, the principle is exactly the same.

Lecture 20

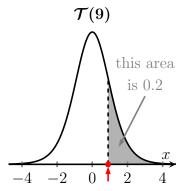

Excel:

T.INV(0.2, 9)

R:

qt(p = 0.2, df = 9, lower.tail = TRUE)

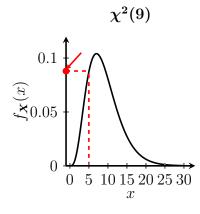

Excel:

T.INV(0.8, 9)

R:

qt(p = 0.2, df = 9, lower.tail = FALSE)

Excel:

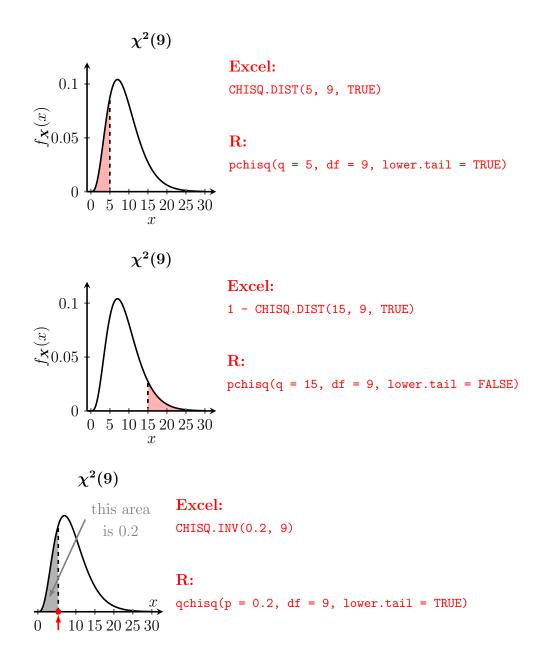

CHISQ.DIST(5, 9, FALSE)

R:

dchisq(x = 5, df = 9)
