## 1 About Calculating E[g(X)]

Recall that a  $random\ variable$  is a function that maps an outcome from the  $sample\ space$  to a real-valued number. Let X and Y be discrete random variables, and

$$\boldsymbol{Y} = g(\boldsymbol{X})$$

Then

$$E[\boldsymbol{Y}] = \sum_{x} g(x) p_{\boldsymbol{X}}(x)$$

Where  $p_{\mathbf{X}}(x)$  is the **probability mass function** (PMF) of the random variable  $\mathbf{X}$ .

*Proof.* According to the definition of *expectation*, we have

$$E[\mathbf{Y}] = \sum_{y} y p_{\mathbf{Y}}(y) \tag{1}$$

Based on the relationship between the random variables X and Y, we have

$$p_{\mathbf{Y}}(y) = \sum_{x \mid g(x) = y} p_{\mathbf{X}}(x) \tag{2}$$

Put the equation (2) into (1), we have

$$\begin{aligned} p_{\mathbf{Y}}(y) &= \sum_{y} y \sum_{x \mid g(x) = y} p_{\mathbf{X}}(x) \\ &= \sum_{y} \sum_{x \mid g(x) = y} y p_{\mathbf{X}}(x) \\ &= \sum_{y} \sum_{x \mid g(x) = y} g(x) p_{\mathbf{X}}(x) \\ &= \sum_{x} g(x) p_{\mathbf{X}}(x) \end{aligned}$$

Lecture 10

If you are not comfortable with the  $\sum$  notation, you can look at the diagram at the right. Since

$$E[\mathbf{Y}] = \sum_{y} y p_{\mathbf{Y}}(y)$$

We need to calculate every single  $y_i p_{\mathbf{Y}}(y_i)$  in order to get  $E[\mathbf{Y}]$ . Here, we use the coloured (red) example as a demonstration.

In this case, we are calculating  $y_3 \cdot p_{\mathbf{Y}}(\mathbf{Y} = y_3)$ . Note  $p_{\mathbf{Y}}(\mathbf{Y} = y_3)$  is the sum of all  $x_i$  such that  $g(x_i) = y_3$ . In this specific example, they are  $\{x_2, x_3, x_5, x_7\}$ . Therefore, we have:

$$y_3.p_{\mathbf{Y}}(\mathbf{Y} = y_3) = y_3.[p_{\mathbf{X}}(x_2) + p_{\mathbf{X}}(x_3) + p_{\mathbf{X}}(x_5) + p_{\mathbf{X}}(x_7)]$$
  
=  $y_3.p_{\mathbf{X}}(x_2) + y_3.p_{\mathbf{X}}(x_3) + y_3.p_{\mathbf{X}}(x_5) + y_3.p_{\mathbf{X}}(x_7)$ 

Note  $y_3 = g(x_2) = g(x_3) = g(x_5) = g(x_7)$ , then the above equation becomes:

$$y_3.p_{\mathbf{Y}}(\mathbf{Y} = y_3) = g(x_2)p_{\mathbf{X}}(x_2) + g(x_3)p_{\mathbf{X}}(x_3) + g(x_5)p_{\mathbf{X}}(x_5) + g(x_7)p_{\mathbf{X}}(x_7)$$
$$= \sum_{i \in \{2,3,5,7\}} g(x_i)p_{\mathbf{X}}(x_i)$$

## 2 About $E[\alpha X + \beta]$

The linear function  $\alpha \mathbf{X} + \beta$  scale the random variable  $\mathbf{X}$  by a constant factor  $\alpha$  and shift everything by a constant factor  $\beta$ . Therefore, we intuitively should expect that:

$$E[\alpha \boldsymbol{X} + \beta] = \alpha E[\boldsymbol{X}] + \beta$$

### School of Life Sciences

#### **BIO210 Biostatistics**

Extra Reading Material

Spring, 2023

Lecture 10

*Proof.* Using the property that  $E[g(\mathbf{X})] = \sum_{x} g(x) p_{\mathbf{X}}(x)$ , we have:

$$E[\alpha \mathbf{X} + \beta] = \sum_{x} (\alpha x + \beta) p_{\mathbf{X}}(x) = \sum_{x} [\alpha x p_{\mathbf{X}}(x) + \beta p_{\mathbf{X}}(x)]$$
$$= \sum_{x} \alpha x p_{\mathbf{X}}(x) + \sum_{x} \beta p_{\mathbf{X}}(x)$$

Since  $\alpha$  and  $\beta$  are constants, we could take them out from the summation:

$$E[\alpha \mathbf{X} + \beta] = \alpha \sum_{x} x p_{\mathbf{X}}(x) + \beta \sum_{x} p_{\mathbf{X}}(x)$$

By definition,  $\sum_{x} x p_{\mathbf{X}}(x) = E[\mathbf{X}]$  and  $\sum_{x} p_{\mathbf{X}}(x) = 1$ , we have:

$$E[\alpha \mathbf{X} + \beta] = \alpha E[\mathbf{X}] + \beta$$

3 About var(X)

The definition is:

$$var(\boldsymbol{X}) = E[(\boldsymbol{X} - E[\boldsymbol{X}])^2]$$

Let's look at this bit by bit. First, for any given random variable X, E[X] is a constant value. Then  $(X - E[X])^2$  is a function of the random variable X, so  $(X - E[X])^2$  is also an random variable. Therefore, it is reasonable to ask: what is the expectation of  $(X - E[X])^2$ ? This is basically  $E[(X - E[X])^2]$ , and it represents how much X deviates from its mean. Very often, it is actually easier to calculate the variance using the following formula:

$$var(\boldsymbol{X}) = E[\boldsymbol{X}^2] - (E[\boldsymbol{X}])^2$$

*Proof.* We start from the definition, use the property of  $E[g(\mathbf{X})]$ , and expand

Lecture 10

the thing inside the parentheses:

$$\operatorname{var}(\boldsymbol{X}) = E[(\boldsymbol{X} - E[\boldsymbol{X}])^{2}] = \sum_{x} (x - E[\boldsymbol{X}])^{2} p_{\boldsymbol{X}}(x)$$

$$= \sum_{x} [x^{2} p_{\boldsymbol{X}}(x) - 2x E[\boldsymbol{X}] p_{\boldsymbol{X}}(x) + (E[\boldsymbol{X}])^{2} p_{\boldsymbol{X}}(x)]$$

$$= \sum_{x} x^{2} p_{\boldsymbol{X}}(x) - \sum_{x} 2x E[\boldsymbol{X}] p_{\boldsymbol{X}}(x) + \sum_{x} (E[\boldsymbol{X}])^{2} p_{\boldsymbol{X}}(x)$$

Since E[X] is a constant value, we can take it out of the summation:

$$\operatorname{var}(\boldsymbol{X}) = \sum_{x} x^{2} p_{\boldsymbol{X}}(x) - 2E[\boldsymbol{X}] \sum_{x} x p_{\boldsymbol{X}}(x) + (E[\boldsymbol{X}])^{2} \sum_{x} p_{\boldsymbol{X}}(x)$$

Now, note that  $\sum_{x} x^2 p_{\boldsymbol{X}}(x) = E[\boldsymbol{X}^2]$  and  $\sum_{x} x p_{\boldsymbol{X}}(x) = E[\boldsymbol{X}]$  by definition, and  $\sum_{x} p_{\boldsymbol{X}}(x) = 1$ . Therefore, we have:

$$var(\mathbf{X}) = E[\mathbf{X}^2] - 2E[\mathbf{X}] \cdot E[\mathbf{X}] + (E[\mathbf{X}])^2$$
$$= E[\mathbf{X}^2] - 2(E[\mathbf{X}])^2 + (E[\mathbf{X}])^2$$
$$= E[\mathbf{X}^2] - (E[\mathbf{X}])^2$$

## 4 About $var(\alpha X + \beta)$

Again,  $\alpha X + \beta$  means scaling the random variable X by a constant factor  $\alpha$  and shifting everything by a constant factor  $\beta$ . When scaling the values, the scaling factor will be exaggerated by the square operation in the variance formula. When shifting the values, the shape of the distribution does not change, so the variance will not be affected by the shifting factor. We should not be surprised that:

$$var(\alpha \boldsymbol{X} + \beta) = \alpha^2 var(\boldsymbol{X})$$

### School of Life Sciences

#### **BIO210 Biostatistics**

Spring, 2023

Lecture 10

*Proof.* We can start with the definition:

$$var(\alpha \mathbf{X} + \beta) = E \left[ \left( (\alpha \mathbf{X} + \beta) - E(\alpha \mathbf{X} + \beta) \right)^{2} \right]$$

Note that  $E(\alpha \mathbf{X} + \beta) = \alpha E[\mathbf{X}] + \beta$ , so we have:

$$\operatorname{var}(\alpha \mathbf{X} + \beta) = E\left[\left(\alpha \mathbf{X} + \beta - \alpha E[\mathbf{X}] + \beta\right)^{2}\right]$$

$$= E[(\alpha \mathbf{X} + \beta - \alpha E[\mathbf{X}] - \beta)^{2}]$$

$$= E[(\alpha \mathbf{X} - \alpha E[\mathbf{X}])^{2}]$$

$$= E[\alpha^{2} \mathbf{X}^{2} - 2\alpha^{2} \mathbf{X} E[\mathbf{X}] + \alpha^{2} (E[\mathbf{X}])^{2}]$$

$$= \sum_{x} [\alpha^{2} x^{2} - 2\alpha^{2} x E[\mathbf{X}] + \alpha^{2} (E[\mathbf{X}])^{2}] p_{\mathbf{X}}(x)$$

$$= \sum_{x} \alpha^{2} x^{2} p_{\mathbf{X}}(x) - \sum_{x} 2\alpha^{2} x E[\mathbf{X}] p_{\mathbf{X}}(x) + \sum_{x} \alpha^{2} (E[\mathbf{X}])^{2} p_{\mathbf{X}}(x)$$

$$= \alpha^{2} \sum_{x} x^{2} p_{\mathbf{X}}(x) - 2\alpha^{2} E[\mathbf{X}] \sum_{x} x p_{\mathbf{X}}(x) + \alpha^{2} (E[\mathbf{X}])^{2} \sum_{x} p_{\mathbf{X}}(x)$$

Again, we already know that  $\sum_x x^2 p_{\boldsymbol{X}}(x) = E[\boldsymbol{X}^2]$ ,  $\sum_x x p_{\boldsymbol{X}}(x) = E[\boldsymbol{X}]$  and  $\sum_x p_{\boldsymbol{X}}(x) = 1$ . Therefore:

$$\operatorname{var}(\alpha \boldsymbol{X} + \beta) = \alpha^2 E[\boldsymbol{X}^2] - 2\alpha^2 E[\boldsymbol{X}] \cdot E[\boldsymbol{X}] + \alpha^2 (E[\boldsymbol{X}])^2$$
$$= \alpha^2 E[\boldsymbol{X}^2] - 2\alpha^2 (E[\boldsymbol{X}])^2 + \alpha^2 (E[\boldsymbol{X}])^2$$
$$= \alpha^2 E[\boldsymbol{X}^2] - \alpha^2 (E[\boldsymbol{X}])^2$$
$$= \alpha^2 (E[\boldsymbol{X}^2] - (E[\boldsymbol{X}])^2)$$

Remember we just proved that  $var(\mathbf{X}) = E[\mathbf{X}^2] - (E[\mathbf{X}])^2$ , so we have:

$$var(\alpha \boldsymbol{X} + \beta) = \alpha^2 var(\boldsymbol{X})$$
